CDI Ignition Schematic Circuit Diagram

A typical CDI module consists of a small transformer, a charging circuit, a triggering circuit and a main capacitor. First, the system voltage is raised up to 250 to 600 volts by a power supply inside the CDI module. Then, the electric current flows to the charging circuit and charges the capacitor.

Capacitor discharge ignition - Wikipedia

A CDI ignition starts by generating a charge and storing it up before sending it out to the spark plug in order to ignite the engine. This power passes through a capacitor and is transferred to an ignition coil that helps boost the power by acting as a transformer and allowing the energy pass through it instead of catching any of it.
